# Studies in soil bacteriology. II. Ammonification in soils and in solutions. By F. L. Stevens and W. A. Withers.

assisted by

## J. C. Temple and W. A. Syme.

[Contributed from the North Carolina Agricultural Experiment Station, West Raleigh, N. C., U. S. A.]

In an earlier article<sup>1</sup>) we have called attention to the fact that inoculation of soils into solutions gives no adequate criterion of the nitrifying powers of soils, owing to the fact that some nitrifying soils fail entirely to nitrify in solutions, and that when in other cases nitrification occurs to some extent in each medium, the amount of nitrification in solutions is not commensurate with the amount of nitrification by the same soils as soils. The question naturally arises whether a similar condition does not exist regarding the process of ammonification.

Ammonification for the present purpose may be defined as the conversion of organic nitrogen into ammoniacal nitrogen. It is probably the most important of all the nitrogen transformations, and accurate knowledge of the conditions which favor it is of permanent importance.

The studies of ammonification which have been made, and they are very numerous and important, have been conducted by isolating organisms and studying the chemical transformations induced by such pure cultures in solutions of artificial composition, or by throwing in various ways, complexes of species in the form of small amounts of soils, or of suspensions derived from soils, into solutions for the purpose of study.

In view of the importance of the subject and in view of the doubts cast upon the validity of results arrived at by present methods of studying ammonification, a series of experiments was undertaken to ascertain whether reliable conclusions regarding the ammonifying power of a soil can be had by study of its effects when inoculated into solutions.

The bacteriological methods were similar to those described in our earlier paper with exception as to the form of nitrogen used<sup>2</sup>) and may be so understood unless special description is given.

### Chemical methods.

To 400 grams of soil were added 10 c. c. of chloroform and water sufficient with that already present in the soil to make 1200 c. c. and the mixture shaken for one hour. After settling somewhat the solution was filtered through a Pasteur-Chamberland filter. An aliquot part was taken. Nitrogen in the form of ammonia was liberated by magnesium oxide, caught in a standard acid solution and titrated with a standard alkaline solution.

When the amount of ammonia was very small is was Nesslerized instead of being titrated.

The amounts are expressed in terms of nitrogen.

Stevens and Withers, Studies in soil soil bacteriology. I. Nitrification in soils and in solutions. (Centralbl. f. Bakt. Abt. II. Bd. XXIII. p. 355.
 Stevens and Withers, l. c.

#### Experiments.

Experiment No. 62 was designed to test the relative rapidity of ammonification in soils as compared with solutions. 240 milligrams of nitrogen as peptone, asparagin and cottonseed meal respectively were placed in 500 c. c. Erlenmeyer flasks, 400 c. c. of tap water was added to each and the whole autoclaved at  $115^{\circ}$  for 15 minutes, then inoculated with 1 c. c. of soil suspension from experiment No. 32<sup>1</sup>) and allowed to stand 9 days.

240 milligrams of nitrogen as peptone, asparagin and cottonseed meal respectively were also mixed with 400 grams of soil No. 1866. The mixture was autoclaved as above and inoculated with 10 c. c. of soil suspension from experiment No. 32 in such a way as to be about two thirds saturated after inoculation and then allowed to stand 12 days. Analyses at the end of the period gave results indicated in table 1.

Table 1. Experiment 62. Medium 400 grams, N 240 mgs. Dec. 12, 1907. Showing a different intensity of ammonification in soils and in solutions.

		Results					
Sample number	Time of incuba- tion Days	Medium Kind	Inocul Kind	um Quantity	Initial nitrogen Form	Ammoniacal nitro gen recovered Per cent Milligram per 100 c. solution	
1938 1939	9 9	Water	Soil Suspension	1 c. c. 1 c. c.	Peptone Asparagin	72.5 ²) 100.0	43.5 60.0
$1940 \\ 1955$	$\begin{array}{c} 9\\12\end{array}$	(Sterile soil	do. do.	1 c. c. 10 c. c.	C. S. M. <sup>3</sup> ) Peptone	$\begin{array}{c} 36.5\\ 26.6\end{array}$	$\begin{array}{c} 21.9\\106.4\end{array}$
$\begin{array}{c} 1956 \\ 1957 \end{array}$	$\begin{array}{c} 12\\12\end{array}$	do. do.	do. do.	10 c. c. 10 c. c.	Asparagin C. S. M.	$32.9 \\ 23.1$	135.6 92.4

It is seen here that though the soil culture received 10 times as large an inoculum, i. e. 10 times as many bacteria and stood 3 days longer, the ammonia produced in it from peptone was  $36 \, {}^0/_0$  of that produced in solution,  $33 \, {}^0/_0$  in the case of asparagin and  $65 \, {}^0/_0$  in the case of cottonseed meal.

While the experiment does not admit of definite conclusions, because of the lack of parallelism in duration of the experiment and amount of inoculum, it certainly indicates very strongly that there is a great difference in the ammonifying power of this soil under the two conditions, i. e. 1) when inoculated into solution, 2) when inoculated into soil itself.

Experiment No. 63. This experiment was precisely like experiment No. 62 except that the inoculum was greenhouse soil, No. 1866.

The results are shown in table 2.

3) C. S. M. signifies cottonseed meal.

<sup>1)</sup> Stevens and Withers l. c.

<sup>2)</sup> The ammonia originally present was determined and found to be of negligable quantity.

#### F. L. Stevens and W. A. Withers,

Table 2. Experiment 63.Medium 400 grams, N 240 mgs., Dec. 7, 1907.Inoculum: suspension of soil 1866.Showing a different intensity of ammonification in soils and in solutions.

		Conditio	Results					
uple 1 ber	Time of incuba-	Medium	Inoculum	Initial nitrogen	Ammoniacal nitrogen recovered			
Sam	tion Days	Kind	Quantity	Form	Per cent	Milligrams per 100 c.c. solution		
$1941 \\ 1942 \\ 1943 \\ 1958 \\ 1958 \\ 1959 \\ 1960$	$9 \\ 9 \\ 9 \\ 12 \\ 12 \\ 12 \\ 12 \\ 12$	Water " St. soil 1866 " " " " " " " " " " " " " " " " " "	1 gram 1 " 1 " 10 grams 10 " 10 " 10 "	Peptone Asparagin Cottonseed meal Peptone Asparagin Cottonseed meal	79.1 <sup>1</sup> ) 78.1 39.8 22.4 28.7 17.5	$\begin{array}{r} 47.5\\ 46.9\\ 23.9\\ 86.9\\ 114.8\\ 70.0 \end{array}$		

Conditions similar to those found in the previous experiment are noted. Based upon the percent of ammonia found; peptone and asparagin are ammonified much more vigorously in solutions than in soil cultures; cottonseed meal likewise, but not with so marked a difference, there being  $28 \,{}^{0}_{0}$ ,  $36 \,{}^{0}_{0}$ ,  $44 \,{}^{0}_{0}$ , as much ammonia produced in soil as in solution with peptone, asparagin, cottonseed meal respectively.

Experiment No. 88. 120 milligrams of nitrogen as cottonseed meal were weighed into 300 c. c. Erlenmeyer flasks, 200 c. c. of tap water added and the whole sterilized.

120 milligrams of nitrogen as cottonseed meal were also mixed with 200 grams of each soil to be tested, flasked and sterilized.

100 grams of the soil to be tested, were well shaken with 200 c. c. of water and 1 c. c. of the suspension was added to each flask of the solution. 1 c. c. of the suspension was also added to 20 c. c. of sterile water, mixed, and this diluted suspension was poured into the sterile soils in the flasks and thoroughly mixed. Soils Nos. 1667, 1867, 1783, 1784, 1931 and 2069 were tested in this manner thereby bringing into 200 grams of solution the same number of organisms and the same species of organisms as were mixed with 200 grams of the soil culture. This arrangement also provided that the organisms in soil media were in soils of the same quality as the soils from which these organisms were derived (identically the same soil except for sterilization). The cultures were incubated 7 days, then analyzed.

The results are given in table 3.

## (See Table 3 p. 779.)

Here again, basing upon the percent of ammonia produced, there is a great difference in the intensity of ammonification in soils and in solutions. In five of the six samples of soil tested, ammonification was again greater in the solution than in the soil cultures, while in one instance ammonification was greater in the soil culture.

Not only is there a difference in rapidity and absolute quantity of ammonification, but the rank of the soils as ammonifiers is different according to whether their ammonifying powers are measured in soils or in solutions.

<sup>1)</sup> Original ammonia was of negligible amount.

6.	1667	6.

Experiment 82. To test relative ammonifying powers of various pure cultures in soil and in solution.

The tests above recited were made with soils, composites of bacterial species. It was deemed advisable to ascertain how far the conclusions indicated by these tests hold true when pure cultures of species are employed. To this end 15 pure cultures of ammonifying organisms were obtained from the most promising sources by plating from soils, cow manure, horse manure and from two labeled cultures from the laboratory stock. All of these pure cultures were inoculated into broth.

120 milligrams of nitrogen as cottonseed meal were weighed into each of sixteen 300 c. c. Erlenmeyer flasks and 200 c. c. of tap water added. An equal amount of cottonseed meal was mixed with 200 grams of soil in each of the sixteen flasks of the same size. All were autoclaved for one hour. Both soils and liquid media were inoculated with 1 c. c. of broth culture. To inoculate the soil flasks, tubes with 20 c. c. of sterile water were first inoculated with 1 c. c. of the broth culture and this dilution poured upon the soil and mixed with it. Ammonia was determined at the end of the fourth day. The results are given in table 4.

th

<sup>1)</sup> Original ammonia was of negligible amount.

Here, basing on percent of ammonia, ammonification was greater in soils than in solutions in the large majority of cases. In only three instances, was ammonification greater in solutions than in soils. Basing upon amount converted per cubic centimeter of solution, the ammonification was greater in soil in every instance. Basing upon percent converted the rank in ammonifying power is as follows:

Rank	teste	in soil	s Rank teste in solution	Source of organism
1.	2085	(6) <sup>1</sup> )	4.	Horse manure
2.	2097	(8)	2.	
3.	2101	(2)	4.	Soil
4.	2107	(8)	8.	Cow manure
5.	2081	(2)	12.	Soil
6.	2087	(8)	7.	Cow manure
6.	2095	(6)	1.	Manure
8.	2091	(2)	9.	Soil
9.	2103	(4)	6.	22
10.	2093	(4)	10.	22
11.	2077	(8)	3.	B. subtilis-culture
12.	2105	(6)	15.	Soil
13.	2079	(80)	11.	B. mycoides-culture
14.	2099	(00)	14.	Horse manure
15.	2089	(90)	13.	Cow "
16.	2083	(4)	16.	72 22
			(See Table 5 p. 782	2, 783.)

5 species hold the same rank in soil and solution; 2 have changed one rank, 2 two ranks, 4 three ranks, 1 five, 1 six and 1 seven ranks; some assuming a higher rank in soils, others higher in solutions.

It is seen from the tabulation that not only is the absolute ammonifying power different in the two media but also that the rank of the organisms as ammonifiers is greatly altered by the mode of test  $^2$ ).

Experiment 105, May 25, 1908. To further test the same point, whether tests made in solutions are fair criteria by which to judge either the absolute or relative ammonifying power of soils, experiments Nos. 105, 200 and 201 were made.

In these experiments the cultures were all made in duplicate and with checks. Four soils were used and with each the ammonifying power was tested in three ways:

1. By inoculation of a suspension into a sterile mixture of cottonseed meal and water (i. e. solution condition).

2. By inoculation of a suspension into sterile soils.

3. By adding the nitrogenous material directly to the live soil. The cultures were kept 10 days, then analyzed.

The results are given in table 5, and summarized in table 6.

(See Table 6 p. 783.)

It is seen here that at the end of 4 days soils Nos. 1931 and 2069 ammonified most vigorously in natural condition. next in sterile soil +suspension and least in the watery suspension: Nos. 1784 and 1667 most in watery suspension. It appears then that some soils will give a maximum test of ammonifying power in the liquid medium, others in the soil medium; that the test made in the liquid is not a fair criterion of ammonifying power. Though the discrepancies are not so great as in the case with the phenomenon of nitrification, they are sufficient to change the rank of soils in ammonifying power, as for example, in the above case where soil 1931 ammonified more than three times as rapidly in soil as in solution as did also soil 2069; while soil 1784 ammonified a

<sup>1)</sup> Parentheses show termination of number of corresponding soil tested in solution.

<sup>2)</sup> While the analyses of all samples were not completed on the same day, the analyses of all cultures inoculated with the same soil were made at the same time. Therefore while the actual rank of these cultures as ammonifiers is not given here, the general conclusion drawn is legitimate.

trifle better in solution than in soil. It is apparent that a proper comparison of the actual field ammonifying power of these three soils could not be had by comparing their ammonifying power in solutions. It is to be noted also that in the original data from which these conclusions are drawn determinations were made in duplicate with control cultures and for the most part with excellent agreement between duplicates. Experiment 209. Aug. 20. 1908. An experiment similar to the preceding was also made with pure culture of several laboratory species and of three "wild" forms, Nos. 5, 7 and 11 isolated from various sources.

To inoculate, 1 c. c. of a 48 hour old broth culture was added to 20 c. c. of sterile water and poured into the soil flask or into the liquid culture, all in strictly parallel manner. The results are presented in table 7.

Table 7.

Test of pure cultures for ammonification in soil and in solution. August 20, 1908. Time, 7 days. Initial nitrogen 120 mg as C. S. M. Inoculum 1 c. c. of 48 hour broth cultures.

As with the composite inoculations of the last experiment some species are seen to ammonify more vigorously in solutions other species in soils.

Organism No. 5 produced less than 7  $^{0}/_{0}$  as much ammonia in solution as in soil; B. megatherium  $32 \, ^{0}/_{0}$ ; B. mycoides  $19 \, ^{0}/_{0}$ . While organism No. 7 produced only  $42 \, ^{0}/_{0}$  as much ammonia in soil as in solution organism No. 11 gave  $46 \, ^{0}/_{0}$ .

Ranking the organisms according to their ammonifying power in solution we have; No. 7, No. 11, subtilis, megatherium, mycoides,

No. 5; in soil, subtilis, megatherium, No. 11, No. 7, mycoides, No. 5.

Thus it is seen that neither the absolute nor the relative ammonifying power of these organisms for soils can be ascertained by testing them in solutions.

#### Summary and Conclusions.

1. Some bacterial soil complexes ammonify faster in solutions.

2. Some bacterial soil complexes ammonify faster in soils.

3. Some pure cultures of organisms ammonify faster in soils, others faster in solutions.

4. The rank of soils, bacterial soil complexes, or of pure cultures is different as measured in soils or in solutions.

The general conclusion stands out clearly as it did regarding nitrification that neither for soils nor pure cultures of organisms can the ammonifying power be adequately determined by testing in solutions; that not even the relative ammonifying power of two soils or two organisms can be determined with certainty by the method of testing in solutions. While there is not so great a discrepancy between results by the solution and the soil method as regards ammonification as obtains regarding nitrification still the discrepancy is sufficient to necessitate using soil as the medium in which to test ammonifying powers in cases where any degree of accuracy is desired and to check all determinations by soil cultures.
